

Architecture and Administration Basics

Workshop Day 2 - Data Modeling

1 Data Modeling

Document Modeling Process

- 1. Understand your application requirements
- Understand the Couchbase APIs
- 3. Map application access paths to best Couchbase API
- 4. Logical data modeling
- 5. Physical data modeling

Understand your application requirements

- Inputs / Outputs
- Request rate, typical and peak
- Latency
- Consistency
- Scope of Aggregations
- Unique constraints
- Data set size & growth rate

Couchbase API	Latency	Throughput	Scalability	Applicability
Key/Value	500us-10ms	> 1M ops/sec	Highest	General, best for high throughput, highly latency sensitive workloads
N1QL	5ms+	> 40K qps	High	General, best for secondary lookups, pushing complex logic to database
Views	10–100ms	< 4K qps	Moderate	Aggregations, best for large scale aggregations (>1B docs) with low latency and moderate latency requirements
Full Text Search	5ms+	> 20K qps	High	Text search, best for natural language queries, relevance ranking

Mapping application requirements to APIs

Application Requirements	Couchbase API
 Very high throughput Latency sensitive Needs strong consistency Large data set / high growth 	Key/Value
Secondary key lookupsOperational aggregationsFiltered queriesAd-hoc queries	N1QL
Report on well defined metricsLarge scale aggregationsLatency sensitive	Views
Find patterns within text fieldsProvide search relevancy rankings	Full text search

2 Data Modeling Considerations

Goals of Data Modeling for N1QL

- Define entities
- 2. Define relationships
- 3. Define document boundaries
- 4. Express relationships

Defining document boundaries entails

- Identifying parent and child objects
- Deciding whether to embed child objects

Identifying Parent and Child Objects

- A parent object has an independent lifecycle
 - It is not deleted as part of deleting any other object
 - E.g. a registered user of a site
- A child object has a dependent lifecycle; It has no meaningful existence without its parent
 - It must be deleted when its parent is deleted
 - E.g. an invoice line item (child of the invoice object)
 - E.g. a comment on a blog (child of the blog object)

- Couchbase provides per-document atomicity
 - If the child and parent must be atomically updated or deleted together, embedding the child facilitates this
 - E.g. if an order line subtotal and order total must be updated together atomically,
 embedding the order line item facilitates this
- There is a performance tradeoff
 - Embedding the child makes it faster to read the parent together with all its children (single document fetch)
 - If the child has high cardinality (its parent has many instances of the child), embedding the child makes the parent bigger and slower to store and fetch
 - If the child has high cardinality (its parent has many instances of the child), embedding the child makes it more expensive to update the parent or the child

Defining Relationships

- Parent-child relationships
 - If we model the child as a separate document and not embedded, we have defined a relationship (parent-child)
- Independent relationships
 - Relationships between two independent objects
 - E.g. a person and a company where they work; deleting one does not delete the other (hopefully)

3 ways to express relationships in Couchbase

- Parent contains keys of children (outbound)
- 2. Children contain key of parent (inbound)
- 3. Both of the above (dual)

High cardinality affects outbound relationships

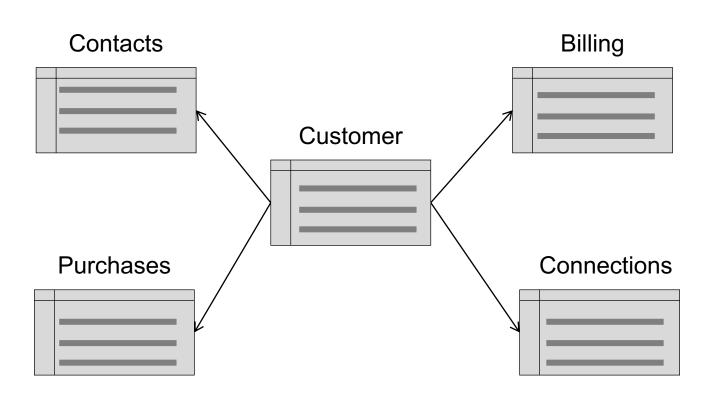

- Makes parent document bigger and slower
- Makes it expensive to load a subset of relationships (e.g. paging through blog comments)

Data Modeling with JSON Objects

Modeling Data in Relational World

- Rich structure
 - Normalize & JOIN Queries
- Relationships
 - JOINS and Constraints
- Value evolution
 - INSERT, UPDATE, DELETE
- Structure evolution
 - ALTER TABLE
 - Application Downtime
 - Application Migration
 - Application Versioning

Table: Customer

CustomerID	Name	DOB
CBL2017	Jane Smith	1990-01-30

- The primary (CustomerID)
 becomes the DocumentKey
- Column name-Column value become KEY-VALUE pair.

Customer DocumentKey: CBL2017

```
{
    "Name" : "Jane Smith",
    "DOB" : "1990-01-30"
}
```

OR

```
{
   "Name": {
        "fname": "Jane",
        "lname": "Smith"
    }
   "DOB" : "1990-01-30"
}
```

Table: Customer

CustomerID	Name	DOB	
CBL2017	Jane Smith	1990-01-30	

Table: Billing

CustomerID	Туре	Cardnum	Expiry
CBL2017	visa	5827	2019-03

Rich Structure & Relationships

- Billing information is stored as a sub-document
- There could be more than a single credit card. So, use an array.

Customer DocumentKey: CBL2017

```
"Name" : "Jane Smith",
    "DOB"
          : "1990-01-30",
    "Billing" : [
           "type" : "visa",
           "cardnum" : "5827-2842-
2847-3909",
           "expiry" : "2019-03"
```

Table: Customer

CustomerID	Name	DOB	
CBL2017	Jane Smith	1990-01-30	

Table: Billing

CustomerID	Туре	Cardnum	Expiry
CBL2017	visa	5827	2019-03
CBL2017	master	6274	2018-12

Value evolution

Simply add additional array element or update a value.

Customer DocumentKey: CBL2017

```
"Name" : "Jane Smith",
    "DOB" : "1990-01-30",
   "Billing" : [
           "type" : "visa",
           "cardnum": "5827-2842-
2847-3909",
           "expiry" : "2019-03"
        },
           "type" : "master",
           "cardnum": "6274-2542-
5847-3949",
           "expiry" : "2018-12"
```

Table: Connections

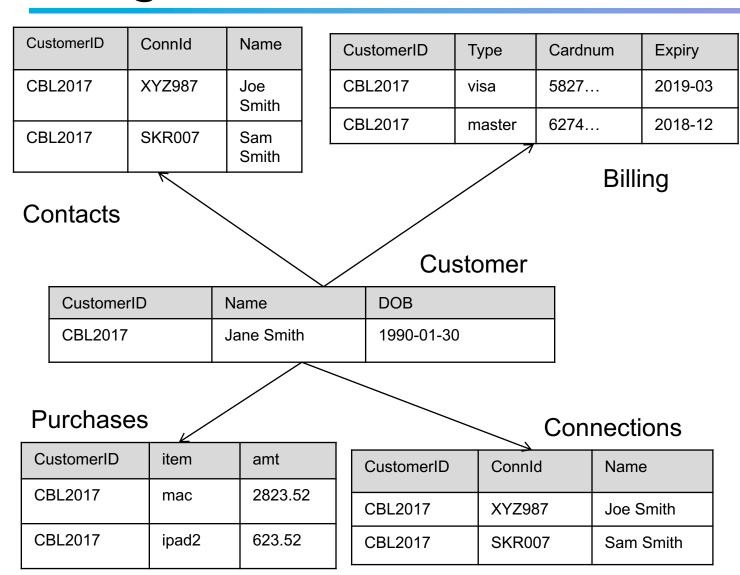

CustomerID	Connld	Name
CBL2017	XYZ987	Joe Smith
CBL2017	SKR007	Sam Smith

Structure evolution

- Simply add new key-value pairs
- No downtime to add new KV pairs
- Applications can validate data
- Structure evolution over time.
- Relations via Reference

Customer DocumentKey: CBL2017

```
"Name": "Jane Smith",
"DOB" : "1990-01-30",
"Billing" : [
        "type"
                  : "visa",
        "cardnum": "5827-2842-2847-3909",
        "expiry" : "2019-03"
        "type"
                  : "master",
        "cardnum": "6274-2542-5847-3949",
        "expiry"
                  : "2018-12"
"Connections" : [
        "ConnId"
                   : "XYZ987",
        "Name"
                   : "Joe Smith"
   },
        "ConnId"
                   : "SKR007",
        "Name"
                   : "Sam Smith"
```

DocumentKey: CBL2017

```
"Name" : "Jane Smith", "DOB" : "1990-01-30",
"Billing":[
    "type" : "visa",
    "cardnum" : "5827-2842-2847-3909",
    "expiry": "2019-03"
    "expiry": "2019-03"
"Connections" : [
   "CustId" : "XYZ987",
"Name" : "Joe Smith"
    "CustId": "PQR823",
    "Name" : "Dylan Smith"
    "CustId": "PQR823",
    "Name" : "Dylan Smith"
"Purchases" : [
```

Models for Representing Data

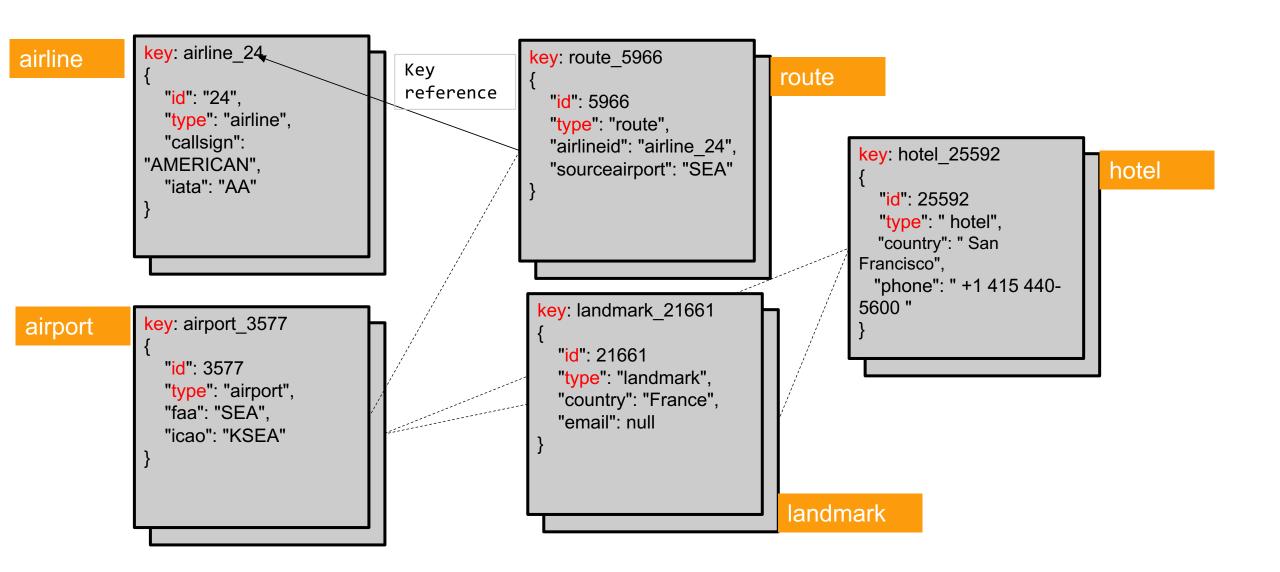

Model	Relational Model	JSON Document Model (NoSQL)
1:1	Foreign KeyDenormalize	Embedded Object (implicit)Document Key Reference
1:N	Foreign Key	Embedded Array of ObjectsDocument key Reference
N:M	■ Foreign Key	 Embedded Array of Objects, arrays of arrays with references

5 Travel Sample

Travel-Sample

Travel-sample: Hotel Document

```
"address": "321 Castro St",
"city": "San Francisco",
"country": "United States",
"description": "An upscale bed and breakfast in a restored house.",
"directions": "at 16th",
  "lon": -122.435
"id": 25390,
"name": "Inn on Castro",
"phone": "+1 415 861-0321",
"price": "$95-$190",
"public likes": ["John Smith", "Joe Carl", "Jane Smith", "Kate Smith"],
    "author": "Mason Koepp",
    "content": "blah-blah",
    "date": "2012-08-23 16:57:56 +0300",
    "ratings": {
      "Check in / front desk": 3,
      "Cleanliness": 3,
      "Location": 4,
      "Overall": 2,
      "Rooms": 2,
      "Service": -1,
      "Value": 2
"state" · "California"
```

Document Key

city: Attributes (key-value pairs)

geo: Object. 1:1 relationship

public_likes: Array of strings:
Embedded 1:many relationship

reviews: Array of objects: Embedded **1:N** relationship

ratings: object within an array

```
> select h.geo from `travel-sample` h
where type = 'hotel' and city = 'San
Francisco' and meta().id = "hotel_25390";

[
    "geo": {
        "accuracy": "ROOFTOP",
        "lat": 37.7634,
        "lon": -122.435
        }
    }
}
```

```
> select reviews[*].ratings from `travel-
sample` h where type = 'hotel' and city =
'San Francisco' and meta().id =
"hotel 25390" ;
   "ratings": [
      "Business service": -1,
      "Check in / front desk": 3,
      "Cleanliness": 3,
      "Location": 4,
      "Overall": 2,
      "Rooms": 2,
      "Service": -1,
      "Value": 2
```

Querying Objects: Accessing data within Objects

```
>select name, city from `travel-sample` h
where geo = {
        "accuracy": "ROOFTOP",
        "lat": 37.7634,
        "lon": -122.435
    };

[
        "city": "San Francisco",
        "name": "Inn on Castro"
        }
]
```

```
select name, city from `travel-sample` h
where geo.accuracy = "ROOFTOP" and geo.lat
between 37.7 and 37.8
and geo.lon between -122.4 and -122.3;
   "city": "San Francisco",
   "name": "Courtyard San Francisco Downtown"
   "city": "San Francisco",
   "name": "Hotel Vitale"
   "city": "San Francisco",
   "name": "South Park"
   "city": "San Francisco",
   "name": "City Kayak"
```

Querying Objects: Search WITHIN

```
select COUNT(1)
FROM system:dual
WHERE ANY v WITHIN {"a":1, "b": "Hello"}
           SATISFIES v = "Hello"
      END;
select COUNT(1)
FROM system:dual
WHERE ANY v WITHIN {"a":1, "b": "World"}
           SATISFIES v = "Hello"
      END;
      "$1": 0
```

```
SELECT COUNT(1)
FROM system:dual
WHERE ANY V WITHIN
  { "a":1,
     "b": {
          "x": "Mercury",
          "y": "Venus",
          "z": "Earth"
           SATISFIES v = "Earth" END;
      "$1": 1
```

6 Document Modeling with JSON Arrays

```
cbq> select distinct type from `travel-sample`;
    "results":
        { "type": "route" },
       { "type": "airport" },
       { "type": "hotel" },
       { "type": "airline" },
       { "type": "landmark" }
    "status": "success",
    "metrics": {
        "elapsedTime": "840.518052ms",
        "executionTime": "840.478414ms",
        "resultCount": 5,
        "resultSize": 202
```

Results from every query is an array.

```
cbq> SELECT * FROM `travel-
sample`WHERE type = 'airport' and
faa = 'BLR';
{
    "results": [],
    "metrics": {
        "elapsedTime": "9.606755ms",
        "executionTime": "9.548749ms",
        "resultCount": 0,
        "resultSize": 0
    }
}
```

JSON Arrays

- Arrays in JSON can contain simple values, or any combination of JSON types within the same array.
- No type or structure enforcement within the array.

```
"Name"
          : "Jane Smith",
"DOB"
          : "1990-01-30",
"hobbies" : ["lego", "piano", "badminton", "robotics"],
"scores" : [3.4, 2.9, 9.2, 4.1],
"legos"
             true,
             9292,
              "fighter 2",
                "name" : "Millenium Falcon",
                "type" : "Starwars"
```

JSON Arrays

```
"Name": "Jane Smith",
"DOB" : "1990-01-30",
"phones": [
"+1 510-523-3529", "+1 650-392-4923"
"Billing": [
   "type": "visa",
    "cardnum": "5827-2842-2847-3909",
   "expiry": "2019-03"
    "type": "master",
    "cardnum": "6274-2542-5847-3949",
    "expiry": "2018-12"
```

Two phone number entries

Billing has two credit card entries, stored as an ARRAY

6 Document Modeling with Arrays

Table: Customer

CustomerID	Name	DOB	
CBL2017	Jane Smith	1990-01-30	

Table: Billing

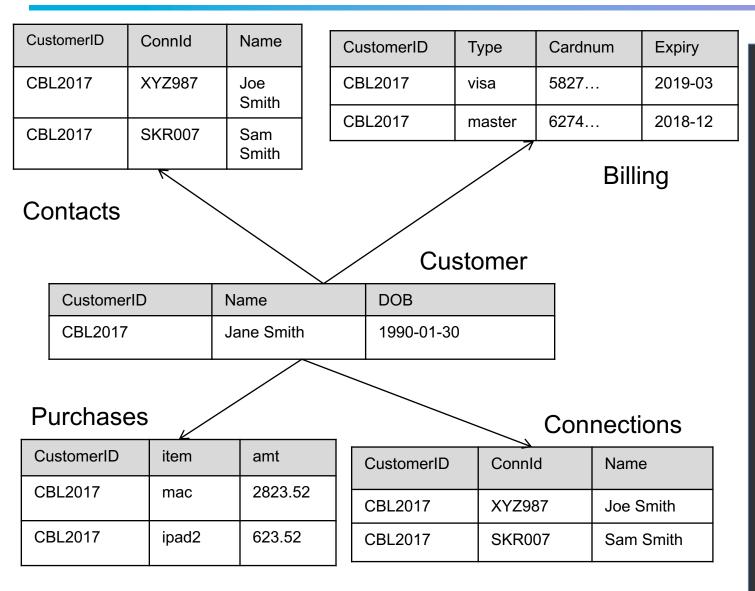

CustomerID	Туре	Cardnum	Expiry
CBL2017	visa	5827	2019-03
CBL2017	master	6274	2018-12

Value evolution

Simply add additional array element or update a value.

```
Customer DocumentKey: CBL2017
   "Name" : "Jane Smith",
   "DOB" : "1990-01-30",
    "Billing" : [
           "type" : "visa",
           "cardnum": "5827-2842-
2847-3909",
           "expiry" : "2019-03"
           "type" : "master",
           "cardnum" : "6274-2542-
5847-3949",
           "expiry" : "2018-12"
```

DocumentKey: CBL2017

```
"Name" : "Jane Smith", "DOB" : "1990-01-30",
"Billing" :
        "type" : "visa",
"cardnum" : "5827-2842-2847-3909",
        "expirv" : "2019-03"
        "type" : "master",
         "cardnum": "6274-2842-2847-3909",
        "expiry" : "2019-03"
"Connections" : [
        "ConnId" : "XYZ987",
        "Name" : "Joe Smith"
        "ConnId" : "SKR007",
"Name" : "Sam Smith"
        "ConnId" : "RGV491",
"Name" : "Rav Smith"
"Purchases" : [
```

Query Arrays

Querying Arrays

- Array Access
 - Expressions
 - Functions
 - Aggregates
- Statements
- Array Clauses

Array access: Expressions, Functions and Aggregates.

    }
}
```

```
SELECT name,
ARRAY_AVG(reviews[*].ratings[*].Overall) AS
avghotelrating
FROM `travel-sample`
WHERE type = 'hotel'
ORDER BY avghotelrating desc
LIMIT 3;
    "avghotelrating": 5,
    "name": "Culloden House Hotel"
  },
    "avghotelrating": 5,
    "name": "The Bulls Head"
  },
    "avghotelrating": 5,
    "name": "La Pradella"
```

8 Array Predicates

Array predicates

- ANY
- EVERY
- ANY AND EVERY
- SATISFIES
- IN
- WITHIN
- WHEN

Array predicates

- Arrays and Objects: Arrays are compared element-wise.
 Objects are first compared by length; objects of equal length are compared pairwise, with the pairs sorted by name.
- IN clause: Use this when you want to evaluate based on specific field.
- WITHIN clause: Use this when you don't know which field contains the value you're looking for. The WITHIN operator evaluates to TRUE if the right-side value contains the left-side value as a child or descendant. The NOT WITHIN operator evaluates to TRUE if the right-side value does not contain the left-side value as a child or descendant.
- EVERY: EVERY is a range predicate that tests a
 Boolean condition over the elements or attributes of a
 collection, object, or objects. It uses the IN and
 WITHIN operators to range through the collection.

- ARRAY_CONTAINS
 - Returns true if the array contains value.

```
SELECT name, t.public_likes
FROM `travel-sample` t
WHERE type="hotel" AND
ARRAY_CONTAINS(t.public_likes,
           "Vallie Ryan") = true;
     "name": "Medway Youth
Hostel",
     "public_likes": [
       "Julius Tromp I",
       "Corrine Hilll",
       "Jaeden McKenzie",
       "Vallie Ryan",
       "Brian Kilback",
       "Lilian McLaughlin",
       "Ms. Moses Feeney",
```

9 UNNEST and NEST

Querying Arrays: UNNEST

 UNNEST: If a document or object contains an array, UNNEST performs a join of the nested array with its parent document. Each resulting joined object becomes an input to the query. UNNEST, JOINs can be chained.

```
SELECT r.author, COUNT(r.author) AS authcount
FROM `travel-sample` t UNNEST reviews r
WHERE t.type="hotel"
GROUP BY r.author
ORDER BY COUNT(r.author) DESC
LIMIT 5;
   "authcount": 2,
   "author": "Anita Baumbach"
   "authcount": 2,
   "author": "Uriah Gutmann"
   "authcount": 2,
   "author": "Ashlee Champlin"
   "authcount": 2,
   "author": "Cassie O'Hara"
   "authcount": 1,
   "author": "Zoe Kshlerin"
```

- NEST is the inverse of UNNEST.
- Nesting is conceptually the inverse of unnesting. Nesting performs a join across two keyspaces. But instead of producing a cross-product of the left and right inputs, a single result is produced for each left input, while the corresponding right inputs are collected into an array and nested as a single array-valued field in the result object.

```
SELECT *
FROM `travel-sample` route
NEST `travel-sample` airline
       ON KEYS route.airlineid
WHERE route.type = 'airline' LIMIT 1;
    "airline": [
        "callsign": "AIRFRANS",
        "country": "France",
        "icao": "AFR",
